# A DIGITAL CAMERA IMAGING MODULE

## BACKGROUND OF THE INVENTION

5

### 1). Field of the Invention

This invention relates to a camera imaging module of the kind which is used for taking digital pictures.

10

### 2). Discussion of Related Art

Digital cameras are becoming increasingly popular for purposes of capturing images digitally, storing the images in memory, and later downloading the stored images to a computer.

15

A digital camera is typically manufactured by first mounting a series of lenses inside a housing under fabrication conditions that are controlled to ensure optimum optical results. The subassembly including the housing and the lenses is then usually shipped to an entity which mounts the camera subassembly to a printed circuit substrate having a light detector array or other imager thereon.

20

The conditions under which the camera subassembly is mounted to the printed circuit substrate is often not controlled to the degree which will ensure optimum

optical results. For example, conditions under which the camera subassembly is mounted to the printed circuit substrate are often not clean enough, resulting in contaminants being trapped inside an enclosure which is defined by the housing and the printed circuit substrate, or for a lens to be mis-aligned with respect to an imager.

Furthermore, the housing usually includes two components which are rotatably engaged with one another. By rotating one of the components relative to the other, utilizing an extraneous device, the total length of the housing can be adjusted and the positioning of the lenses can be adjusted relative to the imager to maintain an image, created on the imager, in focus. Unfortunately, dust can also enter the housing through an interface between the two components.

## SUMMARY OF THE INVENTION

The invention provides a camera subassembly which includes a housing, a window, a lens, at least a first member, and movement imparting apparatus. The housing has a first opening through which light can enter into the housing, and a second, opposing opening. The window closes the first opening so that the housing and the window are formed so that, when the housing is mounted to a substrate so that the substrate closes the second opening, the housing, the first lens, and the board form an enclosure which is substantially sealed against ingress of contaminants. The lens is located within the enclosure. The first member mounts the lens to the housing so that the lens is moveable relative to the housing backward and forward in a direction in which light passes from the first opening through the housing to the second opening. The movement imparting apparatus is at least partially secured to the housing and at least partially secured to the lens and, when operated, causes backward and forward movement of the lens in the direction in which light passes through the housing.

The positioning of the first and second openings relative to one another preferably cannot be changed.

The window may be a refractory lens or a simple window with no optical focusing power.

The camera subassembly may include a printed circuit substrate to which the housing is mounted so that the printed circuit substrate closes the second

opening of the first lens, the housing, the window, and the printed circuit substrate forming an enclosure which is substantially sealed against ingress of contaminants. An imager is mounted within the enclosure to the printed circuit substrate in a position wherein light is focused on the imager after passing  
5 through the window and the lens.

The camera subassembly may include a connector on the printed circuit substrate at a location externally of the enclosure, the connector being within electrical communication with the imager. The socket may have terminals through which at least power and control signals can be supplied to and image  
10 data can be communicated with the imager.

The imager may be a detector array.

The first member may be an elongate member having a first end connected to the housing and a second end connected to the lens.

The first and second elongate members may each coil around an axis  
15 which extends in the direction in which light passes through the housing.

The first elongate member may coil in a first plane, and the second elongate member may coil together with the first elongate member in substantially the first plane.

When viewed in the direction in which light travels through the housing,  
20 the first ends of respectively the first and second elongate members may be connected to the housing on opposing sides of the lens.

The camera subassembly may include a third elongate member, having a

first end connected to the housing, and spaced from the first end of the first elongate member in the direction in which light travels through the housing, and a second end, connected to the lens and spaced from the second end of the third elongate member in the direction in which light travels through the housing, wherein the third elongate member coils around an axis which extends in the direction in which light travels through the housing.

The camera subassembly may include at least one stiffener element which is connected between the first elongate member and the third elongate member.

The camera subassembly may include a fourth elongate member having a first end connected to the housing and spaced from the first end of the second elongate member in the direction in which light travels through the housing, and a second end, connected to the second lens and spaced from the second end of the second elongate member in the direction in which light travels through the housing. The fourth elongate member coils around an axis which extends in the direction in which light travels through the housing.

The first end of the first elongate member may be spaced from the first end of the second elongate member in the direction in which light travels through the housing, and the second end of the first elongate member may be spaced from the second end of the second elongate member in the direction in which light travels through the housing.

The camera subassembly may include a mounting structure within the enclosure, wherein the member is mounted to the mounting structure and the

lens is mounted to the mounting structure, so that the lens is connected to the member via the mounting structure.

The camera subassembly may include at least an additional lens mounted to the mounting structure, the lenses being moveable together with the mounting structure relative to the housing.

The movement imparting apparatus may include at least a first electrical coil which, when energized, causes movement of the lens relative to the housing.

The first electric coil may be mounted within the enclosure.

The first electric coil may be connected to the lens.

The first member may be at least partially conductive and the first electric coil may be electrically accessed through the first member.

The movement imparting apparatus may include at least a second electric coil located within the enclosure and connected to the lens, wherein the second electric coil, when energized, causes movement of the lens relative to the housing.

The first member may be at least partially conductive and the first electric coil may be electrically accessed through the first member, the camera subassembly including a second member which mounts the lens to the housing for movement relative to the housing and the second electric coil may be electrically accessed through the second member.

The movement imparting apparatus may include a permanent magnet, mounted to the housing, which cooperates with the first electric coil to cause

movement of the first electric coil relative to the permanent magnet when the first electric coil is energized.

The invention also provides a camera subassembly which includes a housing, a lens located within the housing, and at least a first member having a first end secured to the housing and a second end secured to the lens so as to mount the lens to the housing, and an elongate section between the first and second ends to allow for backward and forward movement of the lens relative to the housing in a direction of an axis of revolution of the lens.

The at least first member preferably allows for movement of the lens in the direction of the axis of revolution only.

The first elongate member may have a thickness in a direction in the axis of revolution, and a width in a direction transverse to the axis of revolution, the width being more than the thickness.

The first elongate member may coil around the axis of revolution.

The camera subassembly may include a second elongate member having a first end connected to the housing and a second end connected to the lens, wherein the first and second elongate members are spaced from one another in a direction in which the axis of revolution extends, and the second ends of the first and second elongate members are spaced from one another in a direction in which the axis of revolution extends.

The invention also provides a method of assembling a camera subassembly. A housing is mounted to a printed circuit substrate so that the

housing, the printed circuit substrate, and a window jointly define an enclosure which is substantially sealed against ingress of contaminants, and a second lens is mounted within the enclosure by a flexible member which allows for backward and forward movement of the second lens relative to the housing.

- 5           The invention also provides a method of assembling a camera subassembly. An opening into a housing is closed with a window. A lens is located within the housing. The lens and the housing are interconnected by at least a first flexible member which, due to its flexibility, allows for backward and forward movement of the second lens relative to the housing along a direction in
- 10       which light travels through the housing.

## BRIEF DESCRIPTION OF THE DRAWINGS

The invention is further described by way of example with reference to the accompanying drawings wherein:

5

Figure 1 is a cross-sectional side view of a camera subassembly according to an embodiment of the invention;

10

Figure 2 is a plan view of certain components of the camera subassembly of Figure 1; and

Figure 3 is a cross-sectional side view of a camera subassembly according to an alternative embodiment of the invention.

## DETAILED DESCRIPTION OF THE INVENTION

Figure 1 of the accompanying drawings illustrates a camera subassembly 10 according to an embodiment of the invention. The camera subassembly 10 includes a housing 12, a window 14, a first lens 16, a second lens 18, a third lens 20, a fourth lens 22, movement imparting apparatus 24, a printed circuit substrate 26, an imager 28, a first elongate member 30, a second elongate member 32, a third elongate member 34, a fourth elongate member 36, and a mounting structure 38.

The housing 12 is in the form of a tube having a center line 40 extending along the length thereof. The tubular housing 12 has a first opening 42 at one end thereof, and a second opening 44 at an opposing end thereof. The positioning of the first and second openings 42 and 44 relative to one another cannot be changed. The window 14 closes the first opening 42.

The housing 12 is mounted to the printed circuit substrate 26 so that the printed circuit substrate 26 closes the second opening 44. It should be noted that the housing 12, the window 14, and the printed circuit substrate 26 are formed and mounted to one another so as to jointly form an enclosure 46 which is substantially sealed against ingress of contaminants.

The printed circuit substrate 26 includes a connector 48 which is in the form of a plurality of edge fingers, the connector 48 being located externally of the enclosure 46. The imager 28 is in the form of a light detector array which is

mounted to the printed circuit substrate 26 within the enclosure 46. Metal lines 50 are formed on the printed circuit substrate 26 and interconnect to the connector 48 with the imager 28, thus placing the connector 48 within electrical communication with the imager 28. Fingers on the connector 48 are for power and control signals to be provided to and image data to be communicated with the imager 28.

Each elongate member 30, 32, 34 and 36 is made of a spring material such as steel or beryllium copper. The first elongate member 30 has a first end 52 which is secured to the housing 12, and a second end 54 located within the housing 12 and remotely from an inner wall of the housing 12. Similarly, the second, third, and fourth elongate members 32, 34 and 36 each have a respective first end 52 secured to the housing 12, and a respective second end 54 located remotely from an inner wall of the housing.

The first end 52 of the first elongate member 30 is spaced from the first end 52 of the third elongate member 32 in the direction in which the center line 40 extends, and the second end 54 of the first elongate member 30 is spaced from the second end 54 of the third elongate member 34 also in the direction in which the center line 40 extends. Similarly, the first end 52 of the second elongate member 32 is spaced from the first end 52 of the fourth elongate member 36 in the direction in which the center line 40 extends, and the second end 54 of the second elongate member 32 is spaced from the second end 54 of the fourth elongate member 36 in the direction in which the center line 40 extends.

5 The mounting structure 38 is in the form of a tube located within the enclosure 46 and having a center line which substantially corresponds with the center line 40 of the housing 12. One end 56 of the mounting structure 38 is secured to the second end 54 of the first elongate member 30 and to the second end 54 of the second elongate member 32. An opposing end 58 of the mounting structure 38 is secured to the second end 54 of the third elongate member 34 and to the second end 54 of the fourth elongate member 36.

10 The first, second, third, and fourth lenses 16, 18, 20, and 22 are mounted within and directly to the mounting structure 38. Each one of the lenses 16, 18, 20, and 22 has an axis of revolution which substantially corresponds with the center line 40 of the housing 12.

15 Figure 2 illustrates the first and second elongate members 30 and 32 when viewed in the direction in which the center line 40 extends. The first elongate member 30 has a central portion 60 between the first and second ends 52 and 54 thereof which coils in the form of a spiral about the center line 40. The second elongate member 32 has exactly the same construction as the first elongate member 30 and also has a central portion 60 which coils, in the same plane as the first elongate member 30, about the center line 40.

20 The first ends 52 of the first and second elongate members, 30 and 32 respectively, are connected to the housing on opposing sides of the mounting structure 38, and the second ends 54 of the first and second elongate members, 30 and 32 respectively, are connected to the mounting structure 38 on opposing

66020-034960  
sides thereof. Although only the first and second elongate members 30 and 32 are shown in Figure 2, it should be understood that the third and fourth elongate members 34 and 36 have exactly the same constructions as the first and second elongate members 30 and 32 and are positioned relative to one another in exactly the same manner as the first and second elongate members 30 and 32, respectively.

Stiffener elements 62 are provided, each stiffener element 62 being connected between the first elongate member 30 and the third elongate member 34. More stiffener elements 64 are provided, each stiffener element 64 being connected between the second elongate member 32 and the fourth elongate member 36.

The movement imparting apparatus includes first and second stationary portions 66 and 68, and first and second electric coils 70 and 72.

The first electric coil 70 is located externally of and is mounted directly to the mounting structure 38. The first stationary portion 66 includes a permanent magnet 74 which is mounted on an inner wall of the housing 12, and a pole piece 76 extending from the permanent magnet 74 and having a portion located within the first electric coil 70.

The second electric coil 72 is located externally of and is mounted directly to the mounting structure 38 on a side thereof opposing the first electric coil 70. The second stationary portion 68 includes a permanent magnet 74 mounted to an inner wall of the housing 12 on a side thereof opposing the permanent magnet 74

of the first stationary portion 66, and a pole piece 76 extending from the permanent magnet 74 and having a portion located within the second electric coil 72.

The second end 54 of the first elongate member 30 is electrically connected to one end of the first electric coil 70, and the second end 54 of the third elongate member 34 is electrically connected to an opposing end of the first electric coil 70. The first end 52 of the first elongate member 30 is electrically connected via an electrical line 78 to one of the metal lines 50 on the printed circuit substrates 26, and the first end 52 of the third elongate member 34 is similarly connected to one of the metal lines 50. The first and third elongate members 30 and 34 themselves are conductive. Electrical power and ground can thus be provided from the connector 48 respectively through the first and third elongate members 30 and 34 to opposing ends of the first electric coil 70.

In a similar manner, electrical power and ground can be provided through the second and third elongate members 30 and 36 to opposing ends of the second electric coil 72.

The entire camera subassembly 10 may be assembled under controlled conditions and with optical components which will ensure optimum optical performance. A camera subassembly 10 is so provided wherein all components are preassembled according to predetermined design criteria and for example, the imager 28 is optimally chosen and positioned, and the length of the housing is invariable. The camera subassembly 10 may then be mounted within any

72 are relatively light, and the mounting structure 38 is typically a lightweight plastic construction so that focusing is not substantially encumbered by excess mass.

Movement of the mounting structure 38, and the first, second, and third lenses 18, 20, and 22 in the direction in which the center line 40 extends is allowed for due to bending of the elongate members 30, 32, 34, and 36 and corresponding movement of the second ends 54 of the elongate members 30, 32, 34, and 36 in unison in the direction in which the center line 40 extends. The second ends 54 have a tendency to move relatively long distances in the direction in which the center line 40 extends without moving long distances in a direction transverse to the direction in which the center line 40 extends due to the elongate nature of the members 30, 32, 34, and 36.

Each elongate member 30, 32, 34, and 36 has a width  $W$  in a direction transverse to the direction in which the center line 40 extends, and a thickness  $T$  in a direction in which the center line 40 extends. The width  $W$  is substantially more than the thickness  $T$  so that movement of the second ends 54, due to bending of the members 30, 32, 34 or 36, in a direction transverse to the direction in which the center line 40 extends is substantially prevented, while still allowing for sufficient flexibility to allow for movement of the second ends 54 in the direction in which the center line 40 extends.

Any remaining tendency for the second ends 54 to move transversely to the direction in which the center line 40 extends is counteracted because of

symmetry of the members 30, 32, 34, and 36. For example, because the second ends 54 of the first and second elongate members 30 and 32 are mounted on exactly opposing sides of the mounting structure 38, a resultant of forces created on the mounting structure 38 in a direction transverse to the direction in which the center line 40 extends is exactly zero. One of ordinary skill in the art would appreciate that a configuration using three, four, five or more elongate members may also be arranged to ensure cancellation of forces by symmetry.

The first, second, third, and fourth lenses 16, 18, and 20 therefore move backward and forward only in the direction in which the center line 40 extends. The stiffener elements 62 and 64 ensure movement only in the direction in which the center line 40 extends also under conditions wherein the elongate members 32, 34, and 36 are more severely bent i.e., the stiffeners prevent lateral movement due to twisting of the elongate members 32, 34, and 36.

Alignment of the axis of revolution of the first, second, and third lenses 16, 18, and 20 is ensured because of cooperation of the first and second elongate members 30 and 32 with the third and fourth elongate members 34 and 36. For example, a rectangle is formed having corners respectively at the first end 52 of the first elongate member 30, the second end 54 of the first elongate member 30, the second end 54 of the third elongate member 34, and the first end 52 of the third elongate member 34. Bending of the first and third elongate members 30 and 34 results in parallelogram-like movement wherein a line between the second ends 54 of the first and third elongate members 30 and 34 remains

parallel to a line between the first ends 52 of the first and third elongate members 30 and 34. The line between the second ends 54 of the first and third elongate members 30 and 34 thus remains parallel to the center line 40 so that the orientation of the mounting structure 38 remains constant relative to the orientation of the center line 40, and the axes of revolution of the first, second, third, and fourth lenses 16, 18, 20, and 22 remain aligned with the center line 40.

An advantage of having all four lenses 16, 18, 20, and 22 mounted to the mounting structure 38 is that they remain in constant spacial relationship relative to one another. Focusing can be accomplished by moving the lens packet including the mounting structure 38 and the lenses 16, 18, 20, and 22 in unison towards or away from the imager 28. Other embodiments are also possible. One such embodiment is shown in Figure 3 which shows that the fourth lens 22 can be mounted to the housing 12 without intervention of the mounting structure 38. The fourth lens 22 is thus in a stationary position relative to the housing 12 and the lenses 16, 18, and 20 move relative to the fourth lens 22. Such relative movement will affect, and can be used for, focusing.

While certain exemplary embodiments have been described and shown in the accompanying drawings, it is to be understood that such embodiments are merely illustrative and not restrictive of the current invention, and that this invention is not restricted to the specific constructions and arrangements shown and described, since modifications may occur to those ordinarily skilled in the art.

## CLAIMS

What is claimed:

1. A camera subassembly which includes:
  - a housing having a first opening through which light can enter into the housing, and a second, opposing opening;
  - a window which closes the first opening, the housing and the window being formed so that, when the housing is mounted to a substrate so that the substrate closes the second opening, the housing, the first lens, and the substrate form an enclosure which is substantially sealed against ingress of contaminants;
  - a lens located within the enclosure;
  - at least a first member which mounts the lens to the housing so that the lens is movable relative to the housing backward and forward in a direction in which light passes from the first opening through the housing to the second opening; and
  - movement imparting apparatus, at least partially secured to the housing and at least partially secured to the lens, which, when operated, causes backward and forward movement of the lens in the direction in which light passes through the housing.
2. A camera subassembly as in claim 1 wherein the positioning of the first and second openings relative to one another cannot be changed.

1 8. A camera subassembly as in claim 1 wherein the first member is an  
2 elongate member having a first end connected to the housing and second end  
3 connected to the lens.

1 9. A camera subassembly as in claim 8 wherein the elongate member coils  
2 around an axis which extends in the direction in which light passes through the  
3 housing.

1 10. A camera subassembly as in claim 9 wherein the elongate member coils  
2 around an axis of revolution of the lens.

1 11. A camera subassembly as in claim 8 which includes at least a second  
2 elongate member having a first end connected to the housing, and a second end  
3 connected to the lens.

1 12. A camera subassembly as in claim 11 wherein the first and second  
2 elongate members each coil around an axis which extends in the direction in  
3 which light passes through the housing.

1 13. A camera subassembly as in claim 12 wherein the first elongate member  
2 coils in a first plane, and the second elongate member coils together with the first  
3 elongate member in substantially the first plane.

1 14. A camera subassembly as in claim 11 wherein, when viewed in the  
2 direction in which light travels through the housing, the first ends of respectively  
3 the first and second elongate members are connected to the housing on opposing  
4 sides of the lens.

1 15. A camera subassembly as in claim 14 wherein, when viewed in the  
2 direction in which light travels through the housing, the second ends of  
3 respectively the first and second elongate members are connected to the lens on  
4 opposing sides of the lens.

1 16. A camera subassembly as in claim 12 which includes a third elongate  
2 member, having a first end connected to the housing, and spaced from the first  
3 end of the first elongate member in the direction in which light travels through  
4 the housing, and a second end, connected to the lens and spaced from the second  
5 end of the first elongate member in the direction in which light travels through  
6 the housing, wherein the third elongate member coils around an axis which  
7 extends in the direction in which light travels through the housing.

1 17. A camera subassembly as in claim 16 which includes at least one stiffener  
2 element which is connected between the first elongate member and the third  
3 elongate member.

1 18. A camera subassembly as in claim 16 which includes a fourth elongate  
2 member having a first end connected to the housing and spaced from the first  
3 end of the second elongate member in the direction in which light travels  
4 through the housing, and a second end, connected to the second lens and spaced  
5 from the second end of the second elongate member in the direction in which  
6 light travels through the housing, wherein the fourth elongate member coils  
7 around an axis which extends in the direction in which light travels through the  
8 housing.

1 19. A camera subassembly as in claim 11 wherein the first end of the first  
2 elongate member is spaced from the first end of the second elongate member in  
3 the direction in which light travels through the housing, and the second end of  
4 the first elongate member is spaced from the second end of the second elongate  
5 member in the direction in which light travels through the housing.

1 20. A camera subassembly as in claim 1 which includes a mounting structure  
2 within the enclosure, wherein the member is mounted to the mounting structure

3 and the lens is mounted to the mounting structure, so that the lens is connected  
4 to the member via the mounting structure.

1 21. A camera subassembly as in claim 20 which includes at least an additional  
2 lens mounted to the mounting structure, the lenses being movable together with  
3 the mounting structure relative to the housing.

1 22. A camera subassembly as in claim 21 wherein all the lenses through which  
2 the light passes between the first and second openings are mounted to the  
3 mounting structure.

1 23. A camera subassembly as in claim 21 wherein only some of the lenses  
2 through which the light passes between one first and second openings are  
3 mounted to the mounting structure.

1 24. A camera subassembly as in claim 1 wherein the movement imparting  
2 apparatus includes at least a first electrical coil which, when energized, causes  
3 movement of the lens relative to the housing.

1 25. A camera subassembly as in claim 24 wherein the first electric coil is  
2 located within the enclosure.

1 26. A camera subassembly as in claim 25 wherein the first electric coil is  
2 connected to the lens.

1 27. A camera subassembly as in claim 25 wherein the first member is at least  
2 partially conductive and the first electric coil is electrically accessed through the  
3 first member.

1 28. A camera subassembly as in claim 26 wherein the movement imparting  
2 apparatus includes a permanent magnet, mounted to the housing, which  
3 cooperates with the first electric coil to cause movement of the first electric coil  
4 relative to the permanent magnet when the first electric coil is energized.

1 29. A camera subassembly comprising:  
2 a housing;  
3 a lens located within the housing; and  
4 at least a first member having a first end secured to the housing and a  
5 second end secured to the lens so as to mount the lens to the housing, and an  
6 elongate section between the first and second ends to allow for backward and  
7 forward movement of the lens relative to the housing in a direction of an axis of  
8 revolution of the lens.

1 30. A camera subassembly as in claim 29 wherein at least the first member  
2 allows for movement of the lens in the direction of the axes of revolution only.

1 31. A camera subassembly as in claim 29 wherein the first elongate member  
2 has a thickness in a direction of the axis of revolution, and a width in a direction  
3 transverse to the axis of revolution, the width being more than the thickness.

1 32. A camera subassembly as in claim 29 wherein the first elongate member  
2 coils around the axis of revolution.

1 33. A camera subassembly as in claim 31 wherein the first elongate member  
2 coils around the axis of revolution.

1 34. A camera subassembly as in claim 29 which includes a second elongate  
2 member having a first end connected to the housing and a second end connected  
3 to the lens, wherein the first ends of the first and second elongate members are  
4 spaced from one another in a direction in which the axis of revolution extends,  
5 and the second ends of the first and second elongate members are spaced from  
6 one another in a direction in which the axis of revolution extends.

1 35. A method of assembling a camera subassembly, comprising:

2 mounting a housing to a printed circuit substrate so that the housing, the  
3 printed circuit substrate and a window jointly define an enclosure which is  
4 substantially sealed against ingress of contaminants, and a second lens is  
5 mounted within the enclosure by a flexible member which allows for  
6 backwards and forward movement of the second lens relative to the housing.

1 36. A method of assembling a camera subassembly, comprising:  
2 closing an opening into a housing with a window;  
3 locating a lens within the housing; and  
4 interconnecting the lens with the housing by at least a first flexible  
5 member which, due to its flexibility, allows for backward and forward  
6 movement of the second lens relative to the housing along a direction in which  
7 light travels through the housing.

## ABSTRACT OF THE DISCLOSURE

The invention provides a camera subassembly which includes a housing, a window, a lens, at least a first member, and movement imparting apparatus. The housing has a first opening through which light can enter into the housing, and a second, opposing opening. The window closes the first opening so that the housing and the window are formed so that, when the housing is mounted to a substrate so that the substrate closes the second opening, the housing, the first lens, and the board form an enclosure which is substantially sealed against ingress of contaminants. The lens is located within the enclosure. The first member mounts the lens to the housing so that the lens is moveable relative to the housing backward and forward in a direction in which light passes from the first opening through the housing to the second opening. The movement imparting apparatus is at least partially secured to the housing and at least partially secured to the lens and, when operated, causes backward and forward movement of the lens in the direction in which light passes through the housing.

## DECLARATION AND POWER OF ATTORNEY FOR PATENT APPLICATION

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below, next to my name.

I believe I am the original, first, and sole inventor (if only one name is listed below) or an original, first, and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled

## A DIGITAL CAMERA IMAGING MODULE

the specification of which

X is attached hereto.  
\_\_\_\_\_ was filed on \_\_\_\_\_ as  
United States Application Number \_\_\_\_\_  
or PCT International Application Number \_\_\_\_\_  
and was amended on \_\_\_\_\_  
(if applicable)

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claim(s), as amended by any amendment referred to above.

I acknowledge the duty to disclose all information known to me to be material to patentability as defined in Title 37, Code of Federal Regulations, Section 1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, Section 119(a)-(d), of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

<u>Prior Foreign Application(s)</u>			<u>Priority Claimed</u>	
<u>(Number)</u>	<u>(Country)</u>	<u>(Day/Month/Year Filed)</u>	<u>Yes</u>	<u>No</u>
<u>(Number)</u>	<u>(Country)</u>	<u>(Day/Month/Year Filed)</u>	<u>Yes</u>	<u>No</u>
<u>(Number)</u>	<u>(Country)</u>	<u>(Day/Month/Year Filed)</u>	<u>Yes</u>	<u>No</u>
<u>(Number)</u>	<u>(Country)</u>	<u>(Day/Month/Year Filed)</u>	<u>Yes</u>	<u>No</u>

I hereby claim the benefit under title 35, United States Code, Section 119(e) of any United States provisional application(s) listed below

(Application Number)	Filing Date
(Application Number)	Filing Date

I hereby claim the benefit under Title 35, United States Code, Section 120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, Section 112, I acknowledge the duty to disclose all information known to me to be material to patentability as defined in Title 37, Code of Federal Regulations, Section 1.56 which became available between the filing date of the prior application and the national or PCT international filing date of this application:

Title 37, Code of Federal Regulations, Section 1.56  
Duty to Disclose Information Material to Patentability

(a) A patent by its very nature is affected with a public interest. The public interest is best served, and the most effective patent examination occurs when, at the time an application is being examined, the Office is aware of and evaluates the teachings of all information material to patentability. Each individual associated with the filing and prosecution of a patent application has a duty of candor and good faith in dealing with the Office, which includes a duty to disclose to the Office all information known to that individual to be material to patentability as defined in this section. The duty to disclosure information exists with respect to each pending claim until the claim is cancelled or withdrawn from consideration, or the application becomes abandoned. Information material to the patentability of a claim that is cancelled or withdrawn from consideration need not be submitted if the information is not material to the patentability of any claim remaining under consideration in the application. There is no duty to submit information which is not material to the patentability of any existing claim. The duty to disclose all information known to be material to patentability is deemed to be satisfied if all information known to be material to patentability of any claim issued in a patent was cited by the Office or submitted to the Office in the manner prescribed by §§1.97(b)-(d) and 1.98. However, no patent will be granted on an application in connection with which fraud on the Office was practiced or attempted or the duty of disclosure was violated through bad faith or intentional misconduct. The Office encourages applicants to carefully examine:

(1) Prior art cited in search reports of a foreign patent office in a counterpart application, and

(2) The closest information over which individuals associated with the filing or prosecution of a patent application believe any pending claim patentably defines, to make sure that any material information contained therein is disclosed to the Office.

(b) Under this section, information is material to patentability when it is not cumulative to information already of record or being made of record in the application, and

(1) It establishes, by itself or in combination with other information, a prima facie case of unpatentability of a claim; or

(2) It refutes, or is inconsistent with, a position the applicant takes in:

(i) Opposing an argument of unpatentability relied on by the Office, or

(ii) Asserting an argument of patentability.

A prima facie case of unpatentability is established when the information compels a conclusion that a claim is unpatentable under the preponderance of evidence, burden-of-proof standard, giving each term in the claim its broadest reasonable construction consistent with the specification, and before any consideration is given to evidence which may be submitted in an attempt to establish a contrary conclusion of patentability.

(c) Individuals associated with the filing or prosecution of a patent application within the meaning of this section are:

(1) Each inventor named in the application;

(2) Each attorney or agent who prepares or prosecutes the application; and

(3) Every other person who is substantively involved in the preparation or prosecution of the application and who is associated with the inventor, with the assignee or with anyone to whom there is an obligation to assign the application.

(d) Individuals other than the attorney, agent or inventor may comply with this section by disclosing information to the attorney, agent, or inventor.
